

Virtual Repositories

Overview

To simplify access to different repositories, Artifactory allows you to define a virtual repository which is a collection of local, remote and other virtual repositories accessed through a single logical URL.

A virtual repository hides the access details of the underlying repositories letting users work with a single, well-known URL. The underlying participating repositories and their access rules may be changed without requiring any client-side changes.

Public Description

Internal Description

Include Pattern

Exclude Pattern

In addition, in the **Repositories** section of the **Basic** settings screen you select the **Available Repositories** you want to include in the new virtual repository and move them to the **Selected Repositories** list.

This list can be re-ordered by dragging and dropping within the **Selected Repositories** list.

Repositories

Available Repositories		Selected Repositories
libs-release		libs-release-local ✕
libs-snapshot		ext-snapshot-local ✕
p2	◀	remote-repos ✕
p2-virtual	<	
plugins-release	>	
plugins-snapshot	▶	
test-p2		
vri-terra-cotta		

Included Repositories

libs-release-local
ext-snapshot-local
java.net.m1
repo1
gradle-libs

The **Included Repositories** section displays the effective list of actual repositories included in this virtual repository. If any of the available repositories you have selected are themselves virtual repositories, then the **Included Repositories** section will display the local and remote repositories included within them. The **Included Repository** list is automatically updated in case any of the nested virtual repositories change.

The search/resolution order when requesting artifacts from a virtual repository is always:

1. Local repositories
2. Remote repository caches
3. Remote repositories themselves.

The order within these categories is controlled by the order they are presented in the **Selected Repositories** list.

Nesting

Nesting is a unique feature in Artifactory and facilitates more flexibility in using virtual repositories.

You should take care not to create an "infinite loop" of nested repositories. Artifactory analyzes the internal composition of virtual repositories and will issue a warning if the virtual repository can not be resolved due to invalid nesting.

Using Includes and Excludes Patterns

The ability to define and **Includes Pattern** and an **Excludes Pattern** for virtual repositories (especially when nesting is used) provides a powerful tool you can use to manage artifact requests in your organization.

For example, your organization may have its own artifacts which are hosted both internally in a local repository, but also in a remote repository. For optimal performance, you would want these artifacts to be accessed from the local repository rather than from the remote one. To enforce this policy, you can define a virtual repository called "remote-repos" which includes the full set of remote repositories accessed by your organization, and then specify an **Excludes Pattern** with your organization's groupID. In this way, any attempt to access your internal artifact from a remote repository would be rejected.

Consider another example in which you wish to define a virtual repository for your developers, however you wish to keep certain artifacts hidden from them. This could be achieved by defining an **Excludes Pattern** based on groupID, source or version.

Deploying to a Virtual Repository

From version 4.2, Artifactory supports deploying artifacts to a virtual repository. For example you can now use `docker push`, `npm publish`, `NuGet push`, `gem push` Artifactory's REST API and more to deploy packages to a virtual repository.

For more details, please refer to [Deploying Artifacts](#).

Advanced Settings

New Virtual Repository

Basic > **Advanced**

Artifactory Requests Can Retrieve Remote Artifacts

Cleanup Repository References in POMs

Discard active references

Key-Pair

No key-pairs are currently configured. You can add new key-pairs [here](#).

Artifactory Requests Can Retrieve Remote Artifacts	An Artifactory instance may request artifacts from a virtual repository in another Artifactory instance. This checkbox specifies whether the virtual repository should search through remote repositories when trying to resolve an artifact requested by another Artifactory instance. For example, you can use this feature when Artifactory is deployed in a mesh (grid) architecture, and you do not want all remote instances of Artifactory to act as proxies for other Artifactory instances.

Maven, Gradle, Ivy and SBT Repositories

In addition to the above checkbox, these repository types offer the following **Advanced** settings:

Cleanup Repository References in POMs	<p>Public POMs may include direct references to external repositories. If either of the below code samples are present in the POM, Maven dynamically adds an external repository URL to the build which circumvents Artifactory.</p> <pre><project><repositories><repository> or <project><pluginRepositories><pluginRepository></pre> <p>A client side solution for this is to use <code>mirrorOf</code>. For details please refer to Additional "Mirror-any" Setup.</p> <p>This setting gives you the ability to ensure Artifactory is the sole provider of Artifacts in your system by automatically cleaning up the POM file. The three values available for this setting are:</p> <table border="1"><tr><td>Discard Active References</td><td>Removes repository elements that are declared directly under project or under a profile in the same POM that is <code>activeByDefault</code></td></tr><tr><td>Discard Any References</td><td>Removes all repository elements regardless of whether they are included in an active profile or not</td></tr><tr><td>Nothing</td><td>Does not remove any repository elements declared in the POM</td></tr></table>	Discard Active References	Removes repository elements that are declared directly under project or under a profile in the same POM that is <code>activeByDefault</code>	Discard Any References	Removes all repository elements regardless of whether they are included in an active profile or not	Nothing	Does not remove any repository elements declared in the POM
Discard Active References	Removes repository elements that are declared directly under project or under a profile in the same POM that is <code>activeByDefault</code>						
Discard Any References	Removes all repository elements regardless of whether they are included in an active profile or not						
Nothing	Does not remove any repository elements declared in the POM						

Key Pair	A named key-pair to use for automatically signing artifacts. Please refer to WebStart and Jar Signing .

Pre-defined Repositories

Artifactory comes with a set of pre-defined virtual repositories, which reflect binary management best practices as follows.

remote-repos	Aggregation of all remote repositories
lib-releases	libs-releases-local, ext-releases and remote-repos
plugins-releases	plugins-releases-local, ext-releases and remote-repos
libs-snapshots	libs-snapshots-local, ext-snapshots-local, remote-repos
plugins-snapshots	plugins-snapshots-local, ext-snapshots-local, remote-repos
